

Which discovery will the 2026 Nobel Prize in Chemistry be awarded for?

Generated 2026년 10월 6일 오후 3:21

Forecast distribution

Full option labels

1. for the development of massively parallel sequencing-by-synthesis of DNA — Shankar Balasubramanian, David Klenerman
2. for the discovery and development of solid-state perovskite solar cells — Henry J. Snaith, Tsutomu Miyasaka, Nam-Gyu Park
3. for the development of controlled radical polymerization — Krzysztof Matyjaszewski, Mitsuo Sawamoto
4. for the discovery of molecular chaperones that assist protein folding in the cell — Arthur L. Horwich, F. Ulrich Hartl
5. for the development of self-assembled monolayers on solid surfaces — David L. Allara, Ralph G. Nuzzo, George M. Whitesides
6. for the development of palladium-catalyzed carbon-heteroatom bond formation — Stephen L. Buchwald, John F. Hartwig
7. for the development of polymeric and lipid nanoparticle systems for the delivery of drugs and nucleic acids — Pieter R. Cullis
8. for pioneering work on electron transfer in proteins — Harry B. Gray
9. for the development of base editing and prime editing for precise genome editing — David R. Liu
10. for the discovery of targeted protein degradation by small molecules that redirect ubiquitin ligases — Craig M. Crews, Raymond J. Deshaies
11. for the development of transition-metal-catalyzed C-H functionalization reactions — John F. Hartwig, Robert G. Bergman
12. for the development of programmable and chemoenzymatic synthesis of complex carbohydrates and glycoproteins — Chi-Huey Wong
13. for the development of ab initio molecular dynamics — Michele Parrinello, Roberto Car
14. for the development of phosphoramidite chemistry for automated DNA synthesis — Marvin H. Caruthers
15. for the development of mass-spectrometry-based proteomics — John R. Yates III, Matthias Mann, Ruedi Aebersold
16. for the development of efficient organic light-emitting diodes — Ching W. Tang, Steven A. Van Slyke

17. for the development of nanopore methods for single-molecule analysis and sequencing of nucleic acids — Hagan Bayley, David W. Deamer, Daniel Branton
18. for the expansion of the genetic code to incorporate unnatural amino acids into proteins — Peter G. Schultz, Jason W. Chin
19. for their discoveries of chemical communication in bacteria — Bonnie L. Bassler, E. Peter Greenberg
20. for chemical-genetic methods to study protein kinases and the discovery of covalent inhibitors of oncogenic KRAS — Kevan Shokat
21. for the discovery and development of semiconductor photocatalysis for water splitting — Akira Fujishima, Kazunari Domen
22. for the development of accurate exchange-correlation functionals that made density functional theory the workhorse of computational chemistry — John P. Perdew
23. for the discovery of the nuclear receptor superfamily of ligand-regulated transcription factors — Ronald M. Evans
24. for the development of DNA origami and programmable self-assembly of DNA nanostructures — Paul W. K. Rothemund, William M. Shih, Hao Yan
25. for the development of atomic layer deposition — Tuomo Suntola
26. for the development of chemical methods for the synthesis and massively parallel sequencing of DNA — Shankar Balasubramanian, David Klenerman, Marvin H. Caruthers
27. for foundational contributions to the theory and understanding of proton-coupled electron transfer — Sharon Hammes-Schiffer, Thomas J. Meyer
28. for the isolation of stable carbenes and the development of N-heterocyclic carbenes as ligands in catalysis — Anthony J. Arduengo III, Guy Bertrand, Wolfgang A. Herrmann
29. for the development of dye-sensitized and perovskite solar cells — Michael Grätzel, Henry J. Snaith, Tsutomu Miyasaka
30. for the invention of dye-sensitized solar cells — Michael Grätzel

TL;DR

Massively parallel sequencing-by-synthesis of DNA is my leading forecast at 17%, backed by unusually strong discovery-specific recognition. Solid-state perovskite solar cells follow at 8%, and controlled radical polymerization at 6%, supported by the Kyoto Prize and Franklin Institute records. The leading option remains much less likely than all the other listed discoveries combined.

Context

This forecast uses evidence available by October 6, 2026, at 20:10 UTC. Chemistry remains unannounced, with the announcement scheduled for October 7 at 11:45 CEST—09:45 UTC—at the earliest, roughly thirteen and a half hours away (official schedule). I do not use a subsequent Chemistry result.

Under your rules, the probabilities are conditional on the official motivation matching a listed discovery. They therefore allocate nothing to an unlisted discovery or annulment. Discovery wording controls resolution, not the exact laureate names. I apply the larger-share, announcement-order and specificity rules when interpreting overlapping options.

Evidence

The historical backbone is the full published Wolf Chemistry roster from 1978 through 2025. It contains 62 distinct recipients in 36 award cohorts, counting combined-year awards once. Through the completed Chemistry announcement on October 8, 2025, 13 recipients from 12 cohorts had received a Chemistry Nobel. Only four recipients from three cohorts received it in the same calendar year. These are derived counts from an audit of the published roster, Wolf Foundation records and official Nobel register, evaluated at the forecast cutoff.

That distinction matters. A major precursor award identifies exceptional science much better than it identifies the next Nobel announcement. The same-year cohort frequency is 8%, not the much larger observed eventual-conversion frequency. Neither is a direct probability for this question: the historical counts concern people and award cohorts, while this forecast concerns discoveries within a restricted list. Recent cohorts also have less follow-up, and person-based counts miss cases where the discovery receives a Nobel with different recipients. I use this reference class to restrain concentration, not to mechanically set candidate probabilities (Wolf roster; Nobel register).

The Chemistry record also rejects a compulsory rotation between biological chemistry, synthesis and materials. The adjacent organocatalysis and click/bioorthogonal awards provide a clear counterexample. Earlier recognition of a neighboring subject is therefore a discount, not a disqualification (official prize history).

Sequencing-by-synthesis has the strongest combined impact, maturity and recognition case. The Wolf Foundation now recognizes Balasubramanian, Klenerman and Mayer specifically for large-scale DNA sequencing. The same trio received Gairdner recognition and the Princess of Asturias scientific and technical award. These records describe complementary sequencing chemistry and surface-amplification contributions, giving the Academy a coherent discovery narrative and a plausible recipient grouping (Wolf Chemistry record; Gairdner announcement, April 12, 2024; Asturias announcement, May 13, 2026). I read this as strong evidence of Nobel-level standing and Chemistry-category fit, but weaker evidence that this particular year is the year.

Perovskites receive a meaningful current-year update. Miyasaka's Kyoto Prize selection was announced on June 19, 2026, and its rationale recognizes the creation of perovskite photovoltaic technology. The foundation also acknowledges continuing work on operational lifespan and environmental impact. I apply a modest maturity discount, without treating widespread

commercial deployment as a prerequisite for recognition (Kyoto announcement record; award rationale). Controlled radical polymerization has a different strength: an older, chemistry-centered methodology with a compact discovery narrative. The Franklin Institute's historical account dates the independent metal-catalyzed advances to 1995 and jointly recognizes Matyjaszewski and Sawamoto in 2017; that account explicitly carries an April 1, 2017 information vintage (Franklin record).

Self-assembled monolayers have more support than their recent publicity alone suggests. The 2022 Kavli Nanoscience Prize recognized Sagiv, Nuzzo, Allara and Whitesides for this discovery. Clarivate's September 17, 2026 announcement adds current recognition for monolayers, protein electron transfer and precise genome editing. But Clarivate explicitly says its program does not predict recipients in a particular year. Repeated coverage of those selections is therefore one recognition signal, not several independent endorsements (Kavli record; Clarivate announcement; Chemistry selections).

Several biological and therapeutic methods retain substantial probability. Chaperone-assisted folding has longstanding Lasker recognition and fresh Keio recognition for Hartl. Discovering cellular folding machinery is distinct from computational protein prediction, despite the neighboring protein theme (Lasker record; Keio rationale; Nobel history). Drug delivery also extends beyond the named Cullis scenario: Langer's 2026 Welch recognition covers materials that control therapeutic-macromolecule release. The broad delivery option can capture such a motivation even with different laureates (Welch rationale).

Two practical updates prevent me from pushing newer methods too far into the tail. FDA approved the heterobifunctional protein degrader vepdegestrant on May 1, 2026, giving targeted degradation a concrete therapeutic milestone. Gairdner's March 31, 2026 announcement recognizes the proteomics contributions of Yates, Aebersold and Mann. The Gairdner webpage contains an inconsistent opening dateline, so I use the corroborating foundation media release rather than silently accepting that line (FDA announcement; Gairdner announcement; foundation media release).

Base editing and nanoparticle delivery also have clinical proof of concept. NIH's June 3, 2025 account describes a personalized treatment delivered in fatty nanoparticles, but the evidence concerns one patient, not broadly established clinical outcomes. I count that shared milestone once when assessing the two discoveries. Buchwald–Hartwig coupling remains a mature synthetic alternative, with joint Wolf recognition; proximity to the earlier palladium-coupling Nobel reduces its selection weight without making the discoveries identical (NIH account; Berkeley award record; Nobel history).

I also checked the preceding science announcements. Medicine recognized optogenetics, while Physics recognized IceCube and astrophysical neutrinos. Neither official discovery duplicates a listed option. That preserves the candidates' availability; it does not establish which subject

Chemistry will choose (Stanford Medicine announcement, October 5, 2026; Academy Physics announcement, October 6, 2026).

For the numerical estimate, I normalize each supplied probability distribution and use an arithmetic pool with reliability weights of 20%, 35%, 30% and 15%, in the supplied order. Those are my judgmental weights, not fitted historical coefficients. They favor verified milestones, careful discovery boundaries and broad tails over publicity-driven concentration. Shared sources mean agreement does not count as independent confirmation.

I then correct the overlapping resolution scenarios at the family level. My wording assumptions allocate 93% of the pooled sequencing/joint-DNA family to sequencing-by-synthesis and 7% to genuine joint synthesis-and-sequencing recognition. Within the solar family, I allocate 84% to perovskites, 10% to genuine combined dye-sensitized/perovskite recognition and 6% to dye-sensitized cells alone. All other options retain their pooled weights. The final decimal values preserve this calculation and sum to one; they do not imply corresponding epistemic precision.

What's non-obvious

The award stack is less fresh than its year labels suggest. The 2020 Millennium Technology Prize was announced on May 18, 2021, and the 2022 Breakthrough Prize on September 9, 2021. Both are older recognition, not separate recent developments (Millennium announcement; Breakthrough announcement). The fresh Wolf award strengthens sequencing's credentials, but its Nobel-eve publicity is not evidence of a last-minute selection mechanism. Nobel expert consultation occurs in March–May, recommendations are written in June–August and submitted in September, before the early-October vote (official selection process).

The apparent sequencing-symposium advantage is also weaker on inspection. The organizer's account of the 2025 meeting describes optical pooled screening, rather than a focused appraisal of the original sequencing-by-synthesis invention (organizer's report). And synthesis during sequencing does not itself mean recognition of Caruthers's phosphoramidite chemistry, which is a separate enabling technology (Broad Institute account). These distinctions explain the small combined-option probabilities: overlapping labels must not become extra chances to capture the same announcement.

Uncertainties

The largest missing evidence is the committee's comparison of nominees. Nominations, evaluations and deliberations remain confidential for 50 years. I found no authenticated advance Chemistry result in the material reviewed; that is a search finding, not proof that no leak exists (confidentiality rules). A prospective comparison set of equally mature, multiply

awarded discoveries—including nonwinners—would improve calibration more than another retrospective list of successful laureates.

The historical precursor audit is name-based, has unequal follow-up and does not independently verify every recipient biography or announcement timestamp. The exact first-publication time of the latest Wolf winners also remains unverified. I therefore avoid turning the award stack into multiplied likelihood ratios. Official wording can still move probability between neighboring options, especially if the prize combines contributions or uses a broad motivation.

The estimate is sensitive to judgmental pooling weights. Holding the other assessments' relative weights fixed, varying the most concentrated assessment's weight from 10% to 30% moves sequencing's probability to roughly 16%–20%. That is model sensitivity, not a statistical confidence interval. The central conclusion survives: sequencing leads, but the evidence does not justify a dominant favorite.

Question Details

The 2026 Nobel Prize in Chemistry is scheduled to be announced on Wednesday 7 October 2026. Each option names a discovery and the people most closely associated with it. The forecast is conditional on the prize going to one of the listed discoveries; there is no "Other" option.

Resolution Criteria

Resolves to the option whose discovery matches the discovery named in the official motivation of the 2026 Nobel Prize in Chemistry, as published at nobelprize.org. Options are matched by discovery; the people named in an option need not match the laureates exactly. If the prize is divided between two discoveries, only the discovery with the larger share counts; if the shares are equal, the discovery named first in the announcement counts. If more than one option matches, the option that names the awarded discovery most specifically counts. If no option matches that discovery, the question is annulled (the forecast is conditional on one of the listed discoveries).
